International Workshop on Seasonal to Decadal Prediction

Tuesday, 14 May 2013 | Toulouse, FR

# How well can we currently predict short-term climate extremes?

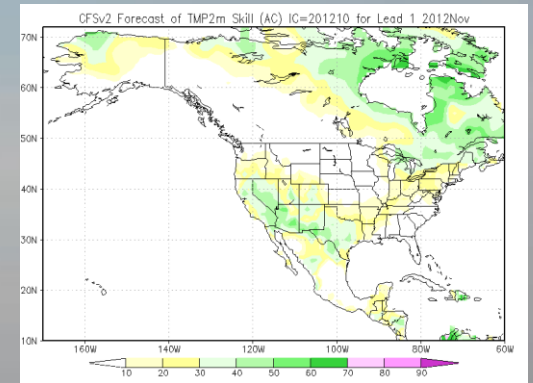

- Short-term climate extremes (STCE): monthly or seasonal means well above or below the mean, at leads of 1 – 8 months.
- Present-day prediction skill and predictability
- 2-meter surface temperature and precip. rate over North and South America; sea-surface temperature in Niño 3.4 region and Atlantic hurricane main development region (MDR)

# Forecasts and Observations

- Climate Forecast System version 2 ensemble mean reforecasts
  - 9-month leads, 1982-2010
  - all 12 initial months
  - regridded to resolution  $1^{\circ} \times 1^{\circ}$  (Saha et al. 2012)
- Tmp2m: GHCN+CAMS, regridded to  $1^{\circ} \times 1^{\circ}$  (Fan and van den Dool 2008)
- Precipitation rate: CPC global Unified Rain-Gauge Database, regridded to  $1^{\circ} \times 1^{\circ}$  (P. Xie et al. 2010).
- Sea-surface temperature: OI-2 (Reynolds et al. 2002), native resolution is  $1^{\circ} \times 1^{\circ}$ .

# Methods

- Systematic error correction to remove model bias: model climatology is removed, and replaced with climatology from observations
- Cross-validation: “CV3RE”
- Verification measures:
  - Anomaly correlation (AC)
  - Root-mean-square error (RMSE)
- AC and RMSE are area-averaged over North America, South America (tmp2m and prate) and Niño3.4 and MDR regions (SST).

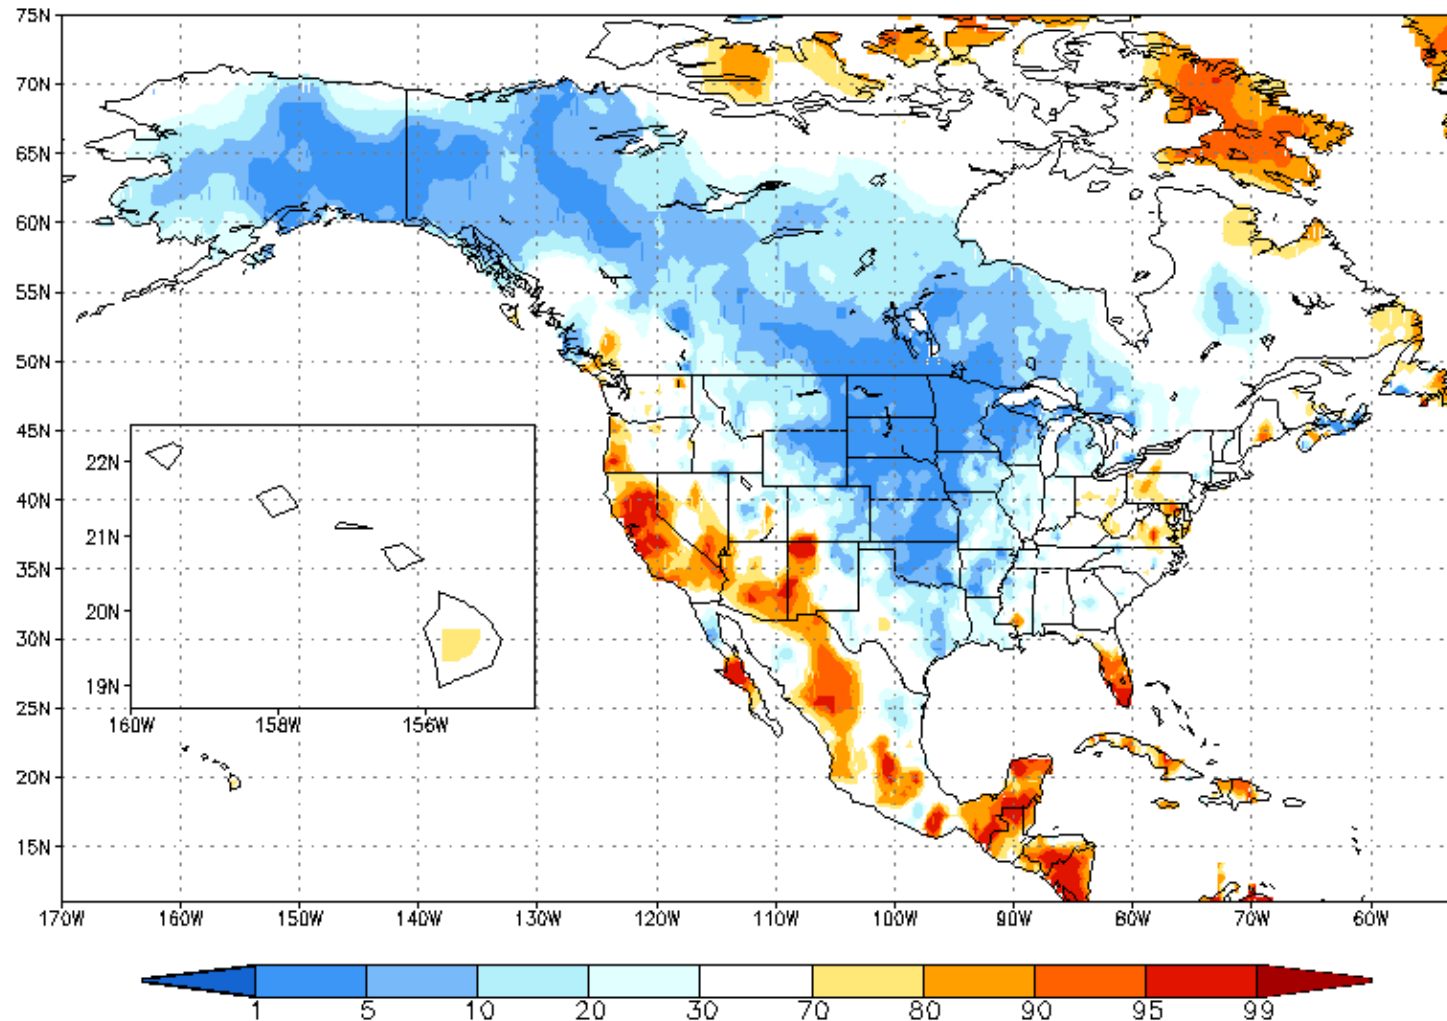

# The definition of extreme

# The definition of extreme

GHCN+CAMS 2m Temperature Ranking Percentile  
APR 2013

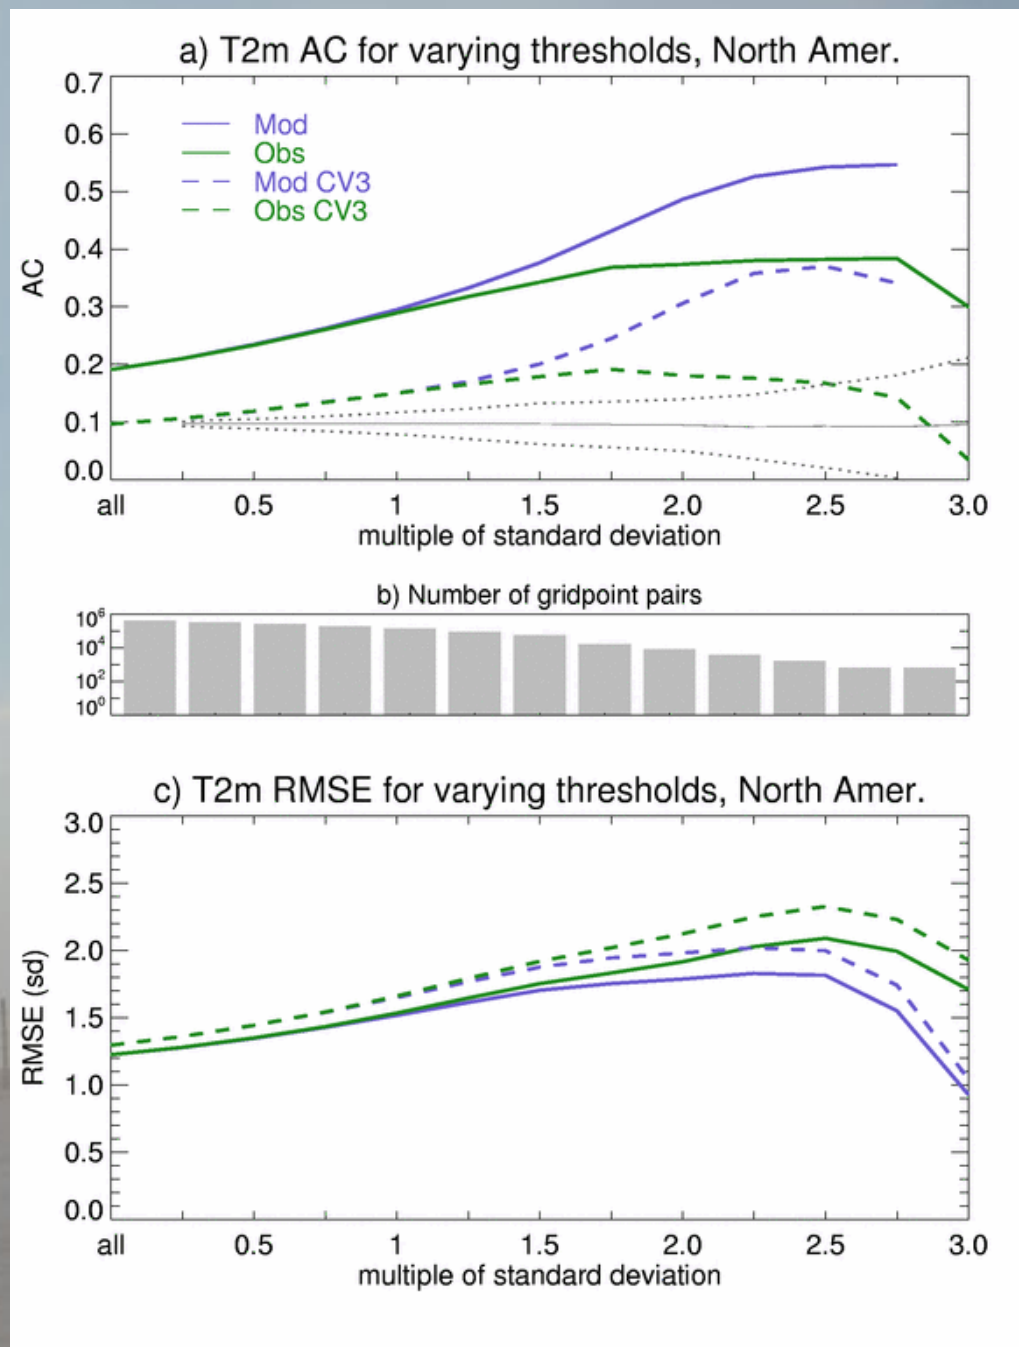

# The definition of extreme

- Gridpoint monthly mean anomaly above/below  $\pm 1.645$  standard deviations
  - Approximately equivalent to 5<sup>th</sup>/95<sup>th</sup> percentiles.
  - Other definitions were tested, with similar skill findings.
- Two scenarios:
  - Extreme is forecast: did it come true?
  - Extreme was observed: was it forecast?

# Tmp2m: North Amer.

- Sliding scale ranging from “all cases” included to  $3.0 \times \text{SD}$ .
- “Mod” = skill assessed for cases where an extreme was forecast
- “Obs” = skill when an extreme was observed
- Permutation tests of 1,000 random subsets

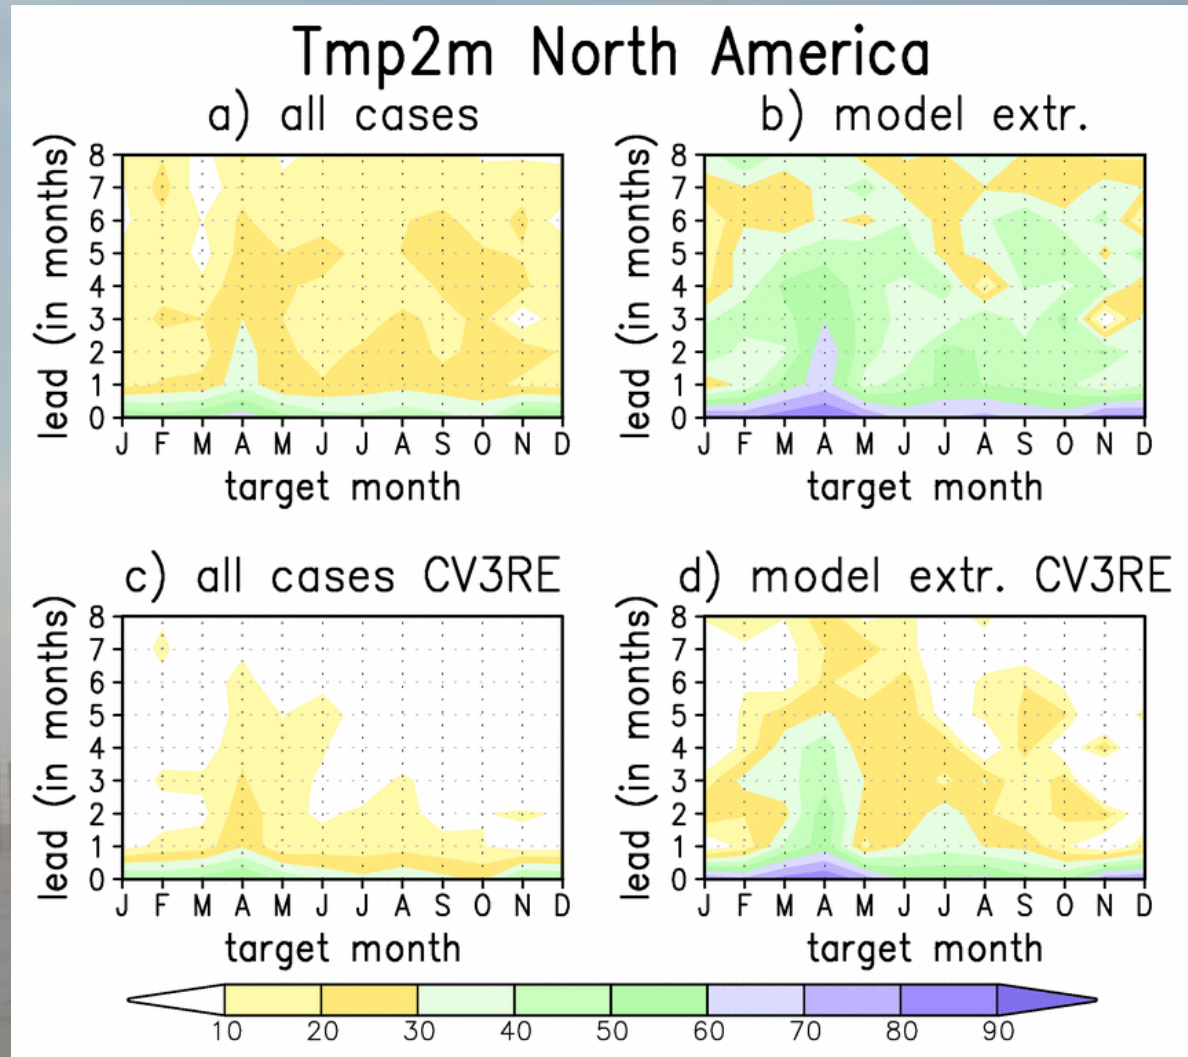

# Tmp2m: South Amer.

T2m skill is higher in  
South America than  
North America

# Tmp2m: North Amer.

- Skill is often a function more of target than lead
- STCE defined here by +/- 1.645 std. dev. threshold

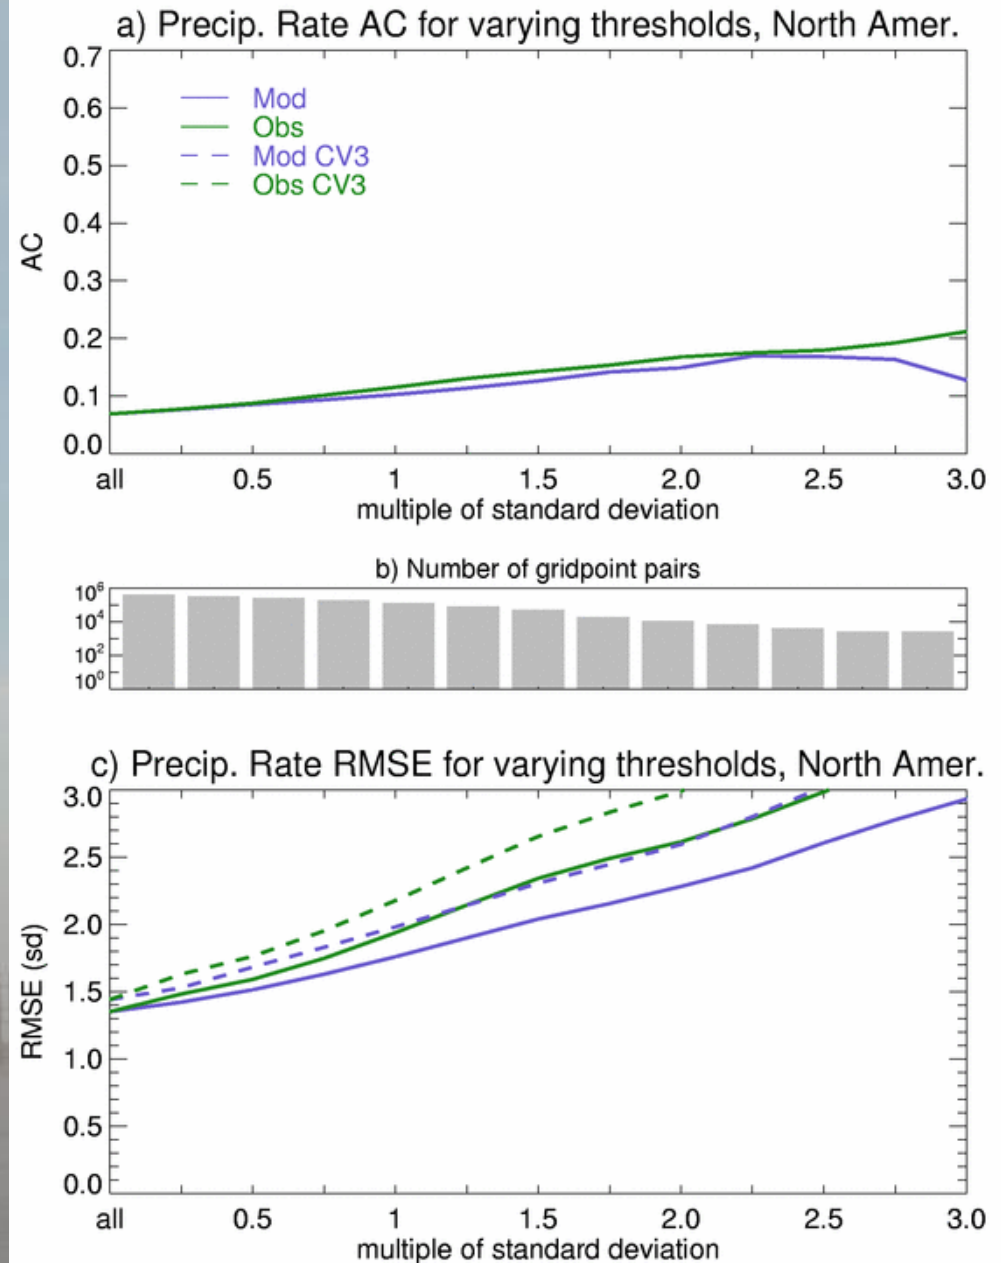

# Tmp2m: South Amer.

# Prate: NA

- Precipitation is very difficult to forecast!
- Cross-validation affects lower scores the most, and leaves us with near-zero scores for precipitation rate

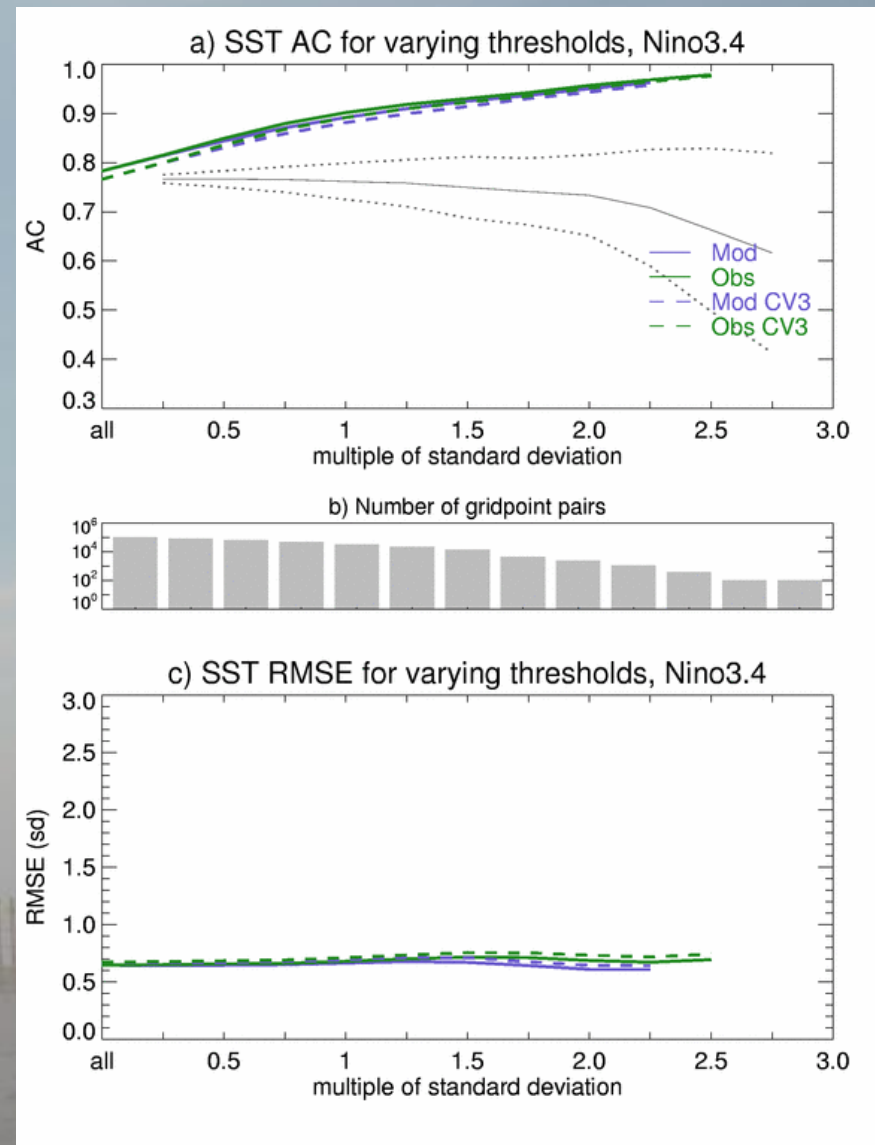

# Precipitation rate: South Amer.

# SST: Niño3.4 Region

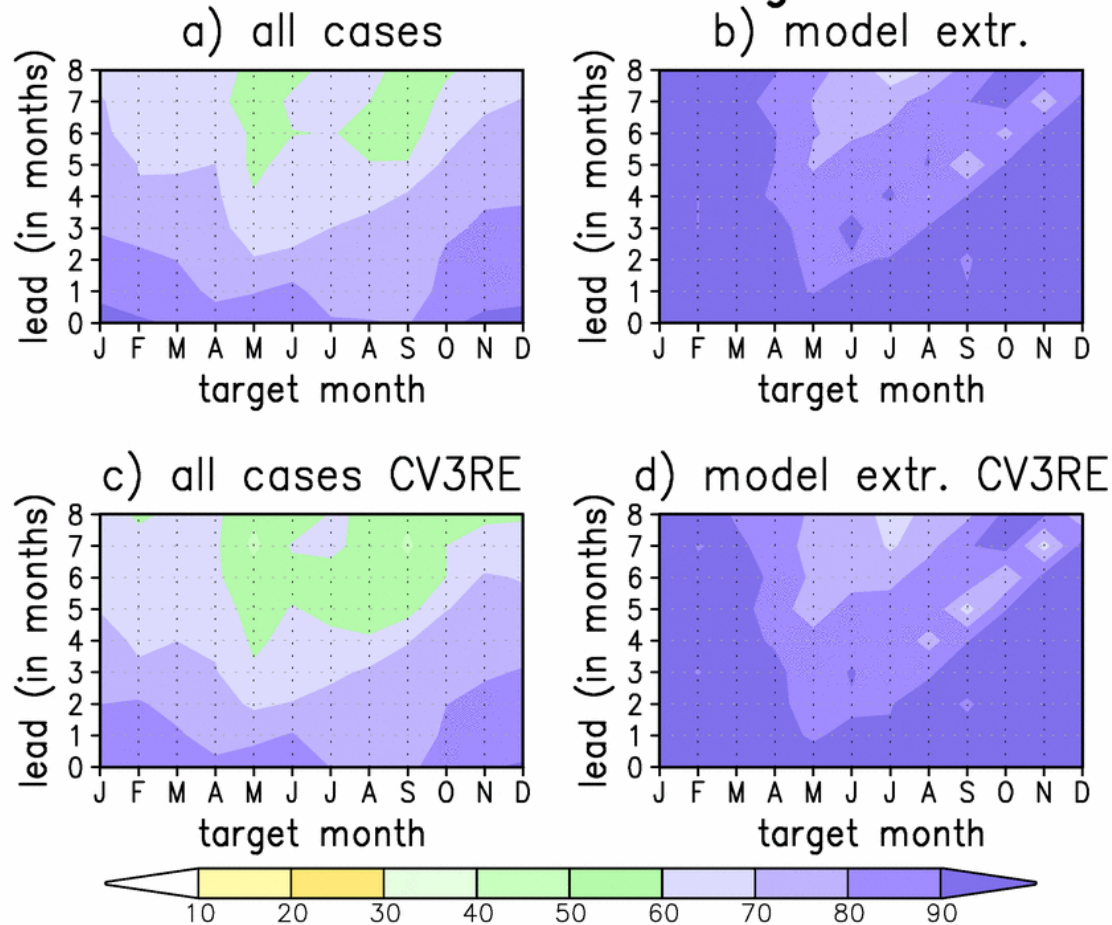

- Higher skill scores are not noticeably reduced by CV
- RMSE is essentially flat with increase in threshold defining extreme

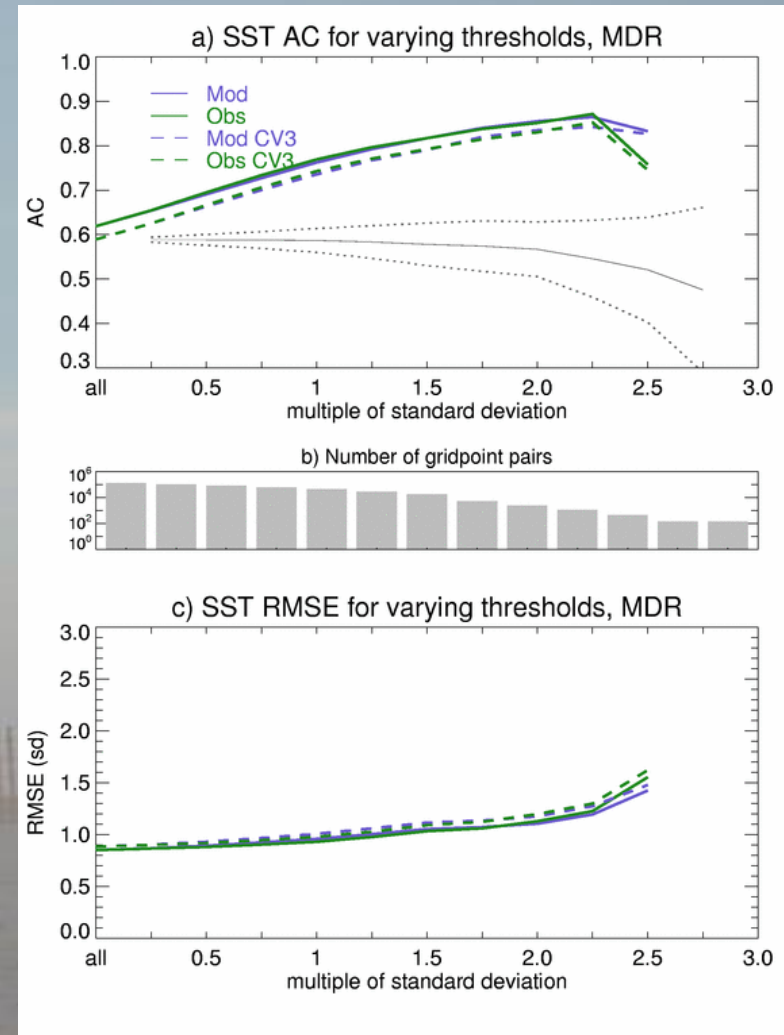

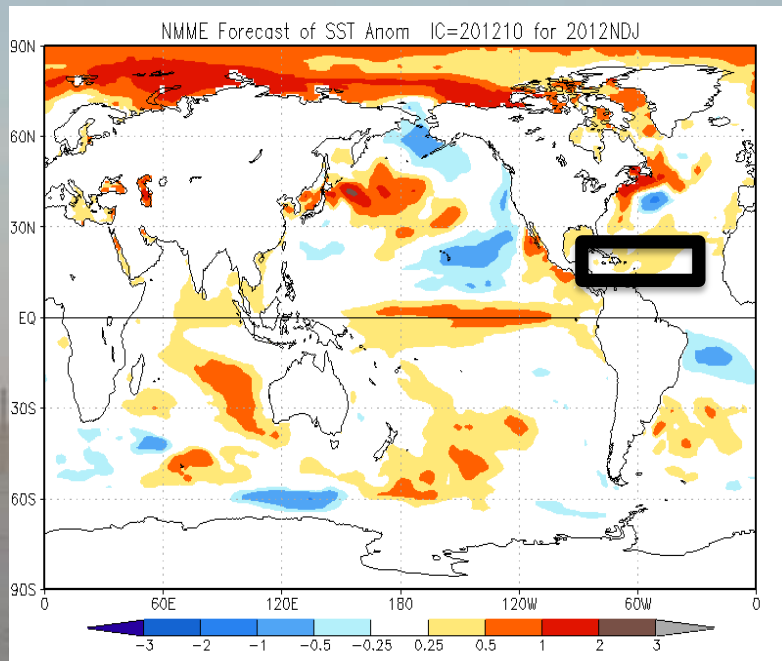

# SST: Niño3.4 Region

## SST Nino3.4 Reg.

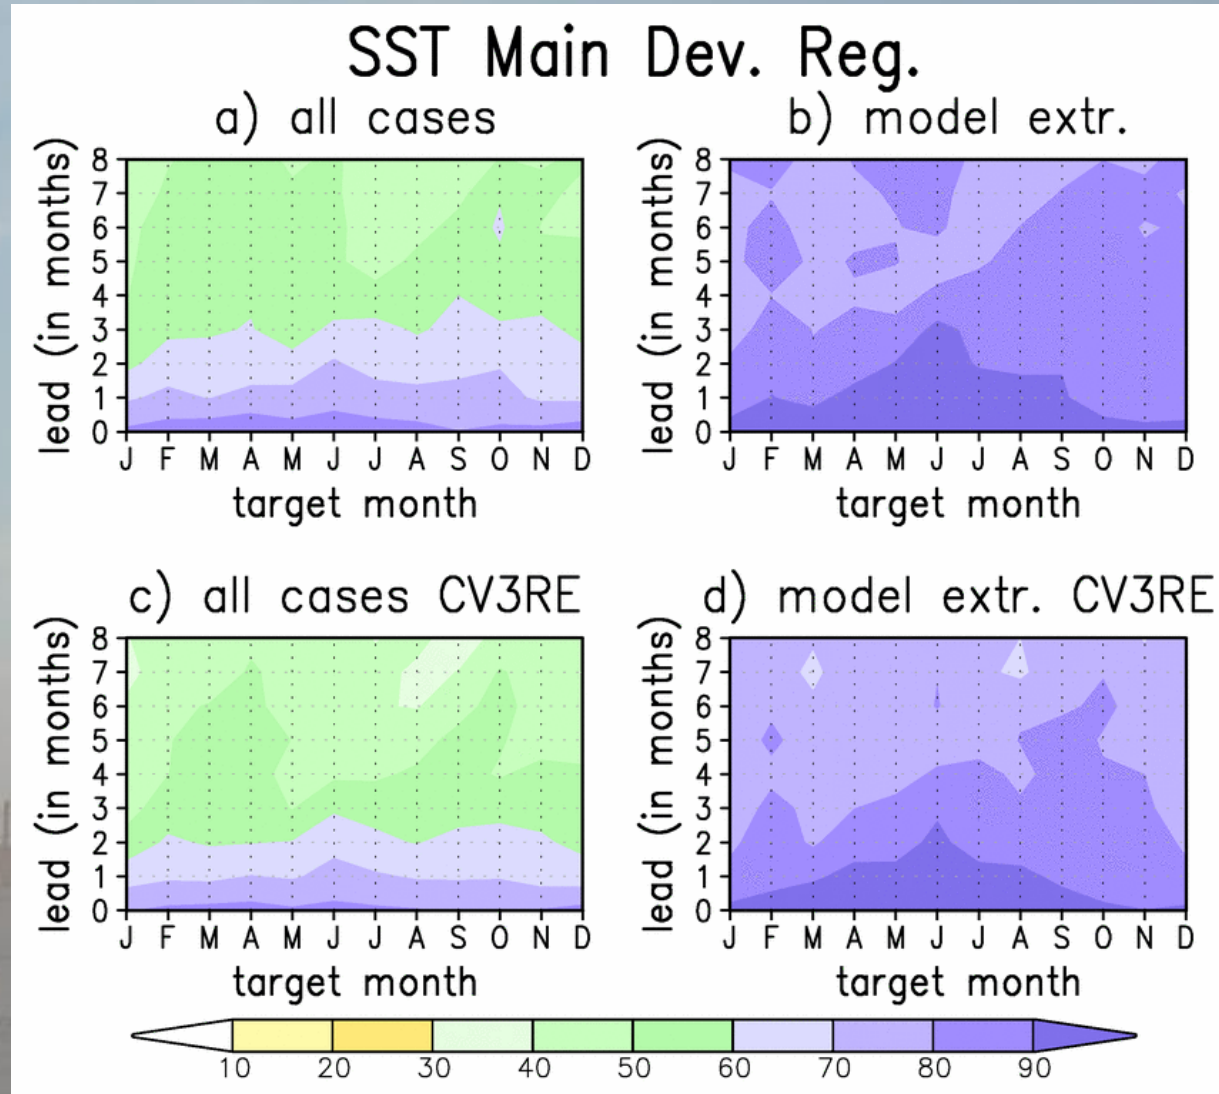

# SST: Atlantic hurricane dev. region

SSTs in this region are important for hurricane forecasting

# SST: Atlantic hurricane dev. region

# Potential predictability

- Test how well the model predicts itself, under “perfect model” assumption.
- Take one member from the ensemble of  $N$  members, verify “prediction” of ensemble mean of  $N-1$  members against this member
- Employ both CFSv1 and CFSv2, as (ideally) the predictability should not depend on the model.

# Tmp2m predictability, North Amer.

g) CFSv2

h) CFSv2 extremes

## SST Main Dev. Reg.

a) all cases

b) model extr.

c) all cases CV3RE

d) model extr. CV3RE

# Summary (1/2)

- Assessed model forecast skill of short-term climate extremes (STCE) in 2 m temperature, precipitation rate, and sea surface temperature using CFSv2, 1982-2010.
- Anomaly correlations for STCEs are routinely higher than for “all cases”.
- RMSE, which can be considered as noise in a signal-to-noise ratio such as the AC, grows more slowly than the threshold: the signal grows despite increased noise.

# Summary (2/2)

- Cross-validation leads to lower ACs. ACs that are already low are affected the most: precipitation ACs are reduced to near zero, while SST ACs are largely unaffected.
- Highest potential predictability for T2m in the first half of the year (both So. and No. Amer.)
- Target months with higher predictability tend to have higher forecast skill, but forecast skill is generally lower than its potential.
